"Blood Cholesterol Permeability of the Aortal Wall of Rabbits in the Progressive, Stationary, and Regressive Stage of Experimental Atherosclerosis and After Cortisone Administration"

Prague, Casopis Lekarů Ceskych, Vol CII, No 31, 5 Aug st 1963, pp 346-350.

Abstract [Authors' English summary: A radioactive 4-<sup>14</sup>C-cholesterol was used to prove that the velocity of the transport of the plasma cholesterol into the wall of aorta was increased about 14 times in the progressive stage and 10 times in the stationary stage of atherosclerosis. No significant difference was found between the regressive stage and control cases. Cortisone has no appreciable effect. The velocity of the serum transport was practically the same in all groups. This points against an increased permeability of the endothelium of aorta for the plasma cholesterol in atheromatous rabbits. The increased cholesterol transport into the inner layers of the aorta wall in atheromatous rabbits is considered to be the consequence of an increased cholesterolaemia.  Accumulation and excretion of iodine-131 in the diagnosis of thyroid disorders. Svatopluk Röhling, Stanislav Vohout, K. Hrabová, and Karel Šilink (Ústřední Endokrinol. Ústav, Prague). *Casopis Lékařů Českých* 94; 1371-4 (1955).—To 8 euthyroid controls, 8 cases with slight oligosymptomatic thyrotoxicosis, 5 with moderately severe thyrotoxicosis, 3 with severe thyrotoxicosis, and 5 with very slight hypothyroidism, a dose of 0.1 mc.  $I^{131}$  (I) was administered orally and the accumulation of I in the thyroid gland was measured *in situ* by Geiger-Müller counting. Urinary excretion of I was also followed. Plots of the results show that the variation of the excretion test leads to overlapping between the various groups of subjects. The accumulation test appears superior; the 24-hr. value is not sufficient for diagnosis, but at least 3 measurements must be made (2, 6, and 24 hrs.).

Rohleder, Jozef

✓ Liquid-air level indicator. Jozef Rohleder (Inst. Technol., Wrocław, Poland). *Roczniki Chem.* 32, 329-33 (1958).

The design of a level indicator for liquid air is described. The app. consists of a differential thermopile, the reference junction of which remains at room temp.; the other junction serves as the detector. A small elec. heater is wound directly on the detector junction and is powered by a 8-v. battery or a small transformer. For accuracy and reliability, the e.m.f. values of the thermopile in the liquid and gas above it should show a large difference. By using a brass-constantan thermopile, differences of the order of a few mv. were obtained. A table gives values of the differences between e.m.f. in liquid air and the gas above it as a function of power supplied to the heater on the indicating junction. Values of the half time for this difference to become const. and the consumption of liquid air resulting from the use of the indicator are reported also. M. P.

Photoelectric conductivity of potassium chloride crystals containing metallic thallium centers. Józef Rohleder (Inst. Technol., Wrocław, Poland). *Roczniki Chem.* 28, 297-8 (1954) (English summary). Monocrystals of KCl contg. small amts. of TlCl were treated in sealed tubes with K vapor. Afterwards the crystals were heated *in vacuo* to remove excess K; so that they should contain metallic Tl centers only. The crystals show a considerable photocurrent in the visible region with a max. about 600 m $\mu$ . The absorption coeff. increases with increasing radiation frequency and does not pass the max. in the visible region.

Title : Band Model of KCl Crystals, Containing Centers of Metallic Thallium (KCl, Tl).

Orig Pub : Roczn, chem., 1959, 33, No 2, 419-427

Abstract : It is proposed that in the KCl lattice one should distinguish between two position of Tl atoms: 1) Tl atoms around which are located vacant anion sites; 2) Tl atoms, near which there are no corresponding vacant sites. The former have an acceptor character, and are responsible for the photoconductivity. The concentration is on the order of  $10^{13}$  --  $10^{14}$   $\text{cm}^{-3}$  and they are located 2.26 ev above the edge of the valence band. The other levels are

Card 1/2

POLAND/Electronics - Semiconductors.

H-

Abs Jour : Ref Zhur Fizika, No 3, 1960, 6453

located 5.5 ev below the conduction band and are responsible for optical absorption. Upon absorption of light with  $h\nu = 4.0$  ev, only excitation of the centers takes place and there is no photoconductivity. Upon absorption of light with  $h\nu = 5.2$  ev, weak photoconductivity is produced, possibly due to the presence of thermal effects. -- A. Shneyder

Title : Further Investigations of the External Photoeffect in KCl Crystal, Containing Centers of Metallic Thallium (KCl, Tl)

Orig Pub : Roczn, Chem., 1959, 33, No 2, 411-418

Abstract : From the sign of the thermal emf, it was determined that the current carriers in crystals KCl, Tl are holes. In the volt-ampere characteristics of the photocurrent, up to gradients of  $2 \times 10^4$  v/cm, there is no saturation and one can therefore assume that the charge is  $Q = NwE/d$ , where N is the concentration of the current carriers, e the carrier charge, E the intensity of the field,  $wE$  the average shift, and d the distance between electrodes. Using

Card 1/2

- 86 -

this formula, it is possible to determine the product  $Nw$ . Assuming the  $w$  is the same as for the electrons in crystals with F centers and (according to Pohl's data) its concentration of  $\approx 10^{12}$  to  $10^{13}$   $\text{cm}^{-3}$ , which is  $10^6$  to  $10^7$  times smaller than the concentration of Tl. Experiment shows also that the current density (meaning also  $Nw$ ) is almost independent of the concentration of Tl. It is concluded therefore that as the concentration is increased N increases and  $w$  decreases. The latter may be connected with the fact that some of the Tl atoms play the part of traps. -- A. Shneyder

Rohm Z. Research into the Resistance of Chocolate to Storage.

„Przyczynek do badań nad trwałością czekolady”. Przemysł Spożywczy. No. 2, 1958, pp. 72—77, 3 figs., 8 tabs.

Researches into the resistance of chocolate to storage demonstrated that: 1) chocolate of suitable composition, i.e., produced from pure cacao-seeds and cacao-oil, sugar, and possibly vanilla, shows

after one year in store no organoleptic changes of importance; 2) the chemical changes taking place in chocolate concern the cacao oil contained in it and affect the following properties of the oil: the Reichert-Meisler, hydroxyl, peroxide, oxide and rancidity numbers and eplhydrin aldehyde content; 3) paper wrapping affects some external organoleptic qualities of chocolate, for instance, surface, gloss, etc.; 4) addition to chocolate of pea-nuts, even in minimal quantities and in any form, has a deleterious effect on the resistance to storage and the quality of the product.

**Rohm Z. The Quality of the Confectionery Filling.**

„Zagadnienie jakości pomady cuklerycznej”, *Przemysł Rolny i Spożywczy*, No. 10, 1953, pp. 350—355, 6 figs., 9 tabs.

The author discusses certain technical problems concerning the production of good quality confectionery fillings. He concludes that the stability of the soft consistency of the filling can be markedly increased. He discusses the water content of the filling, the size of the sugar crystals, the time during which the filling is kept in store, and the influence of enzyme preparations. The author affirms that confectionery filling to which enzyme preparations have been added reveals optimal quality properties after 15—20 days and has a water content of 7—10% and a softening point of 0.25—0.50 kg/cm<sup>2</sup>.

Theories of the precipitation-hardening of metallic alloys.  
F. Röhner. *Berg- u. hüttenmänn. Monatsh. monist. Hoch-  
schule Leoben* 66, 21-5(1951).--The various theories pro-  
pounded since discovery of pptn. hardening in 1906 are  
critically surveyed, and it is concluded that even at the  
present no entirely satisfactory explanation can be given.  
The view that in analogy to cold-working, internal stresses  
cause the hardening phenomenon can no longer be held in  
the light of recent investigations of cold-deformation hard-  
ening. It seems more likely that the pptn.-hardening  
mechanism is due to a homogeneous reinforcing of the  
matrix. M. Hartenheim

SZITA, Jozsef, Dr, ROHNY, Bela, Dr, SCHNEIDER, Agnes, Dr; National Public Health Institute and Central State Hospital (Orszagos Kozegeszsegugyi Intezet es Kozponti Allami Korhaz).

"Experiences With Central Sterilization Used in the Central State Hospital for Two Years."

Budapest, Magyar Sebeszet, Vol XVI, No 4, Aug 1963, pages 209-216.

Abstract: [Authors' Hungarian summary] The effectiveness of the central sterilization unit, established in 1960 in the Central State Hospital, is evaluated after 2 years of existence. The problems of location, equipment, personnel and instrument supply, the method of collection and distribution of the material and the work procedures performed by the unit are described. The problems remaining to be solved are pointed out. It is concluded that a central sterilization unit is effective for the decrease of hospital infections and thus contributes to the raising of the standards of care. Although the initial establishment is expensive, the elimination of surgical infections, the increased insurance of sterility and the saving in working hours will return the initial expenditures in a short time. 13 Hungarian, 13 Western references.

**Diagram of the recrystallisation of silver.** J. Cochral-ski and J. Rohozinska. *Widomosci Tech. Metalurg. Metaloz.* 4, 82-47(1937).—Test cubes were cut out of a Ag plate (99.9% Ag, 0.075% Fe) which was first cold-rolled and later heated at 800°. These cubes were cold-formed, their length decreasing 2.88%, and recrystd. during half an hr. at different temps. (100-900). After etching with a soln. contg. about 10% H<sub>2</sub>O<sub>2</sub> and 20% NH<sub>4</sub>, the size of the grains was measured. The diagram of the recrystn. of Ag varies from the diagrams for most of the metals so far examd.; test samples recrystd. at 900° and compressed by 10% show a min. size of the grains. Fourteen illustrations, 5 references.

**Psychrophilic wine yeasts.** V. Hulaš and E. Rohrer  
(Agr. Research Inst., Prague, Czech.). *Sborník Českoslo-  
v. Akad. Zemědělsk. 21*, 63-73 (1918). The morphologi-  
cal and physiol. properties of these wine yeasts of the  
Fendant and Herrliberg family were examd. The cul-  
tures differ to some extent in their morphology, spore  
formation, and resistance to alc. At 1-5° these yeasts are  
suitable for wine production. In the manuf. of sparkling  
wines fermented in bottles, the soly. of CO<sub>2</sub> is increased  
and the wine stone is almost all pptd. during fermentation.  
The danger of becoming "sour" especially in the case of  
red wines and the alc. losses during fermentation are  
greatly reduced.

ROHRSETZLER, S.

Effect of freezing on the sol of  $As_2S_3$ . A. Buzágh and S. Rohrsetzer (Eötvös Loránd Univ., Budapest, Hung.). *Acta Chim. Acad. Sci. Hung. 1959*, 164, 107-11 (1959).— $As_2S_3$  sols contg. added NaOH or  $Na_2S$  do not coagulate but change color from yellow to a very stable deep red. The intensity of the red color increases with time in the frozen state. The time of formation of the red sols depends on temp. and changes according to a max. curve. The red  $As_2S_3$  sol shows thixotropy and streaming birefringence. These properties are due to formation of anisodimensional secondary particles. It is proposed to call the oriented coagulation caused by freezing "cryotropy." At higher temp. the red sols disaggregate into yellow sols of almost the original properties.
